

SLG59M1709V

An Ultra-small, 4 mΩ, 4 A Load Switch
with Multiple Protection Features

General Description

Operating from a 2.5 V to 5.5 V power supply and fully specified over the -40 °C to 85 °C temperature range, the SLG59M1709V is a high-performance 4 mΩ, 4 A single-channel nFET load switch with adjustable inrush current control which is achieved by adjusting the V_{OUT} slew rate with an external capacitor. Using a proprietary MOSFET design, the SLG59M1709V achieves a stable 4 mΩ RDS_{ON} across a wide input/supply voltage range. Incorporating two-stage current protection as well as thermal protection, the SLG59M1709V is designed for all 0.8 V to 5.5 V power rail applications. The SLG59M1709V is packaged in a space-efficient, low thermal resistance, RoHS-compliant 1.6 mm x 2.5 mm STQFN package

Features

- Low Typical RDS_{ON} nFET: 4 mΩ
- Maximum Continuous Switch Current: Up to 4 A
- Supply Voltage: 2.5 V ≤ V_{DD} ≤ 5.5 V
- Wide Input Voltage Range: 0.8 V ≤ V_{IN} ≤ V_{DD}
- Capacitor-adjustable Start-up and Inrush Current Control
- Two-stage Overcurrent Protection:
 - Fixed threshold, 8 A Active Current Limit
 - Fixed 0.5 A Short-circuit Current Limit
- Operating Temperature: -40 °C to 85 °C
- Low θ_{JA}, 16-pin 1.6 mm x 2.5 mm STQFN Packaging
- Pb-Free / Halogen-Free / RoHS compliant

Pin Configuration

**16-pin FC-STQFN
(Top View)**

Applications

- Notebook Power Rail Switching
- Tablet Power Rail Switching
- Smartphone Power Rail Switching

Block Diagram

SLG59M1709V

An Ultra-small, 4 mΩ, 4 A Load Switch
with Multiple Protection Features

Pin Description

Pin #	Pin Name	Type	Pin Description
1	VDD	Power	With an internal 1.9 V $V_{DD(UVLO)}$ threshold, VDD supplies the power for the operation of the load switch and internal control circuitry where its range is $2.5\text{ V} \leq V_{DD} \leq 5.5\text{ V}$. Bypass the VDD pin to GND with a 0.1 μF (or larger) capacitor
2	NC	NC	No Connect
3-7	VIN	MOSFET	Drain terminal of Power MOSFET (Pins 3-7 fused together). Connect a 10 μF (or larger) low ESR capacitor from this pin to GND. Capacitors used at VIN should be rated at 10 V or higher.
8-12	VOUT	MOSFET	Source terminal of Power MOSFET (Pins 8-12 fused together). Connect a low ESR capacitor (up to 500 μF) from this pin to GND. Capacitors used at VOUT should be rated at 10 V or higher.
13	NC	NC	No Connect
14	CAP	Input	A low-ESR, stable dielectric, ceramic surface-mount capacitor connected from CAP pin to GND sets the V_{OUT} slew rate and overall turn-on time of the SLG59M1709V. For best performance, the range for C_{SLEW} values are $2\text{ nF} \leq C_{SLEW} \leq 22\text{ nF}$. Capacitors used at the CAP pin should be rated at 10 V or higher.
15	GND	GND	Ground
16	ON	Input	A low-to-high transition on this pin closes the load switch. ON is an asserted-HIGH, level-sensitive CMOS input with $ON_{V_{IL}} < 0.3\text{ V}$ and $ON_{V_{IH}} > 0.85\text{ V}$. While there is an internal pull down circuit to ground ($\sim 4\text{ M}\Omega$), connect this pin to the output of a general-purpose output (GPO) from a microcontroller or other application processor.

SLG59M1709V Power-Up/Power-Down Sequence Considerations

To ensure glitch-free power-up under all conditions, apply V_{DD} first, followed by V_{IN} after V_{DD} exceeds 1.9 V. Then allow V_{IN} to reach 90% of its max value before toggling the ON pin from Low-to-High. Likewise, power-down in reverse order.

If V_{DD} and V_{IN} need to be powered up simultaneously, glitching can be minimized by having a suitable load capacitor. A 10 μ F C_{LOAD} will prevent glitches for rise times of V_{DD} and V_{IN} higher than 2 ms.

If the ON pin is toggled HIGH before V_{DD} and V_{IN} have reached their steady-state values, the load switch timing parameters may differ from datasheet specifications.

The slew rate of output V_{OUT} follows a linear ramp set by a capacitor connected to the CAP pin. A larger capacitor value at the CAP pin produces a slower ramp, reducing inrush current from capacitive loads.

SLG59M1709V Current Limiting Operation

The SLG59M1709V has two types of current limiting triggered by the output V_{OUT} voltage.

1. Standard Current Limiting Mode (with Thermal Shutdown Protection)

When the V_{OUT} voltage > 300 mV, the output current is initially limited to the Active Current Limit (I_{ACL}) specification listed in the Electrical Characteristics table. The ACL monitor's response time is very fast and is triggered within a few microseconds to sudden (transient) changes in load current. When a load current overload is detected, the ACL monitor increases the FET resistance to keep the current from exceeding the load switch's I_{ACL} threshold. During active current-limit operation, V_{OUT} is also reduced by $I_{ACL} \times RDS_{ON(ACL)}$. This observed behavior is illustrated in the timing diagrams on Pages 7 and 8.

However, if a load-current overload condition persists where the die temperature rises because of the increased FET resistance, the load switch's internal Thermal Shutdown Protection circuit can be activated. If the die temperature exceeds the listed $THERM_{ON}$ specification, the FET is shut OFF completely, thereby allowing the die to cool. When the die cools to the listed $THERM_{OFF}$ temperature threshold, the FET is allowed to turn back on. This process may repeat as long as the output current overload condition persists.

2. Short Circuit Current Limiting Mode (with Thermal Shutdown Protection)

When the V_{OUT} voltage < 300 mV (which is the case with a hard short, such as a solder bridge on the power rail), the load switch's internal Short-circuit Current Limit (SCL) monitor limits the FET current to approximately 500 mA (the I_{SCL} threshold). While the internal Thermal Shutdown Protection circuit remains enabled and since the I_{SCL} threshold is much lower than the I_{ACL} threshold, thermal shutdown protection may become activated only at higher ambient temperatures.

SLG59M1709V Start-up Inrush Current Considerations with Capacitive Loads

In distributed power applications, the SLG59M1709V is generally implemented on the outboard or downstream side of switching regulator dc/dc converters with internal overcurrent protection. As an adjustable output voltage slew-rate load switch, it is important to understand the start-up operation of the SLG59M1709V with capacitive loads. An equivalent circuit of the SLG59M1709V's slew-rate control loop with capacitors at its VIN and VOUT pins is shown in Figure 1:

SLG59M1709V

An Ultra-small, 4 mΩ, 4 A Load Switch
with Multiple Protection Features

SLG59M1709V Start-up Inrush Current Considerations with Capacitive Loads (continued)

Figure 1. SLG59M1709V's Equivalent Slew-rate Control Loop Circuit.

For a desired $V_{OUT(SR)}$ slew-rate ($V_{OUT(SR)}$), a corresponding C_{SLEW} value is selected. At the V_{OUT} pin and with $ON = LOW$, the internal FET is OFF, V_{OUT} is initially at 0V, and there is no stored charge on C_{LOAD} . When a low-to-high transition is applied to the IC's ON pin, an internal current source (I_1) is enabled which, in turn, charges the external slew-rate capacitor, C_{SLEW} . The SLG59M1709V's internal micropower op amp sets the circuit's $V_{OUT(SR)}$ based on the slew rate of the nodal voltage at its non-inverting pin (the voltage at the CAP pin).

As a function of $V_{OUT(SR)}$ and C_{LOAD} , a 1st-order expression for the circuit's FET current (and inrush current) when a low-to-high transition on the ON pin is applied becomes:

$$\text{Start-up Current } I_{DS} \text{ or } I_{INRUSH} = V_{OUT(SR)} \times C_{LOAD}$$

From the expression above and for a given $V_{OUT(SR)}$, C_{LOAD} determines the magnitude of the inrush current; that is, for large values of C_{LOAD} , large inrush currents can result. If the inrush currents are large enough to trigger the overcurrent protection of an upstream dc/dc converter, the system can be shut down.

In applications where the desired $V_{OUT(SR)}$ is fast and C_{LOAD} is very large ($>200 \mu F$), there is a secondary effect on the observed $V_{OUT(SR)}$ attributed to the SLG59M1709V's internal short-circuit current limit monitor (its SCL monitor). If the resultant inrush current is larger than the IC's I_{SCL} threshold, the SCL current monitor limits the inrush current and the current to charge C_{LOAD} until the I_{SCL} OFF threshold is crossed ($\sim 0.3V$). During the time the SCL monitor's been activated, the inrush current profile may exhibit an observable reduction in $V_{OUT(SR)}$ as shown in Figure 2 where C_{SLEW} was set to 4nF and 470 μF was chosen for C_{LOAD} .

SLG59M1709V

An Ultra-small, 4 mΩ, 4 A Load Switch
with Multiple Protection Features

SLG59M1709V Start-up Inrush Current Considerations with Capacitive Loads (continued)

Figure 2. A SLG59M1709V with C_{SLEW} set to 4nF and 470μF for C_{LOAD} . C_{LOAD} -to- C_{SLEW} ratio is greater than 33,600. Note that the internal SCL monitor's been triggered and $V_{OUT(SR)}$ is reduced until V_{OUT} reaches ~0.3V.

A closer analysis of the IC's internal slew-control large-scale yields the following:

$$\frac{I_{SCL}}{C_{LOAD}} = M_{SR} \times \frac{I_1}{C_{SLEW}}$$

where

I_{SCL} = IC's short-circuit current limit threshold, typically 0.5A;

M_{SR} = An internal slew-rate multiplier from the IC's CAP pin to the VOUT pin;

I_1 = An internal current source to charge the external capacitor (C_{SLEW}).

Rearranging the equation to isolate both C_{LOAD} and C_{SLEW} yields the following:

$$\frac{C_{LOAD}}{C_{SLEW}} = \frac{I_{SCL}}{I_1 \times M_{SR}}$$

For the SLG59M1709V device, the right-hand side of the expression is approximately 33,600 after taking into account part-to-part variations because of process, voltage, and temperature.

Referring to the configuration of Figure 2's scope capture, the C_{LOAD} -to- C_{SLEW} ratio is 117,500 (470μF/4nF) where it is evident that the SCL monitor circuit is charging C_{LOAD} shortly after a low-to-high ON transition. If it is desired to avoid a reduction in $V_{OUT(SR)}$, the choices are decreasing C_{LOAD} and/or increasing C_{SLEW} so that the ratio is always less than 33,600 including taking into account external capacitor tolerances for initial accuracy and temperature.

As shown in Figure 3, it was chosen to reduce $V_{OUT(SR)}$ by increasing C_{SLEW} to 15nF while keeping C_{LOAD} at 470μF. With this configuration, the ratio of C_{LOAD} to C_{SLEW} is about 31,333 (smaller than 33,600). Upon a low-to-high transition on the ON pin, the V_{OUT} increases smoothly with no evidence of SCL monitor's interaction.

SLG59M1709V

An Ultra-small, 4 mΩ, 4 A Load Switch
with Multiple Protection Features

SLG59M1709V Start-up Inrush Current Considerations with Capacitive Loads (continued)

Figure 3. A SLG59M1709V with C_{SLEW} set to 15nF and 470μF retained for C_{LOAD} . C_{LOAD} -to- C_{SLEW} ratio is smaller than 33,600. Note smooth V_{OUT} transition.

Power Dissipation

The junction temperature of the SLG59M1709V depends on different factors such as board layout, ambient temperature, and other environmental factors. The primary contributor to the increase in the junction temperature of the SLG59M1709V is the power dissipation of its power MOSFET. Its power dissipation and the junction temperature in nominal operating mode can be calculated using the following equations:

$$PD = RDS_{ON} \times I_{DS}^2$$

where:

PD = Power dissipation, in Watts (W)

RDS_{ON} = Power MOSFET ON resistance, in Ohms (Ω)

I_{DS} = Output current, in Amps (A)

and

$$T_J = PD \times \theta_{JA} + T_A$$

where:

T_J = Junction temperature, in Celsius degrees ($^{\circ}C$)

θ_{JA} = Package thermal resistance, in Celsius degrees per Watt ($^{\circ}C/W$)

T_A = Ambient temperature, in Celsius degrees ($^{\circ}C$)

SLG59M1709V

An Ultra-small, 4 mΩ, 4 A Load Switch with Multiple Protection Features

Power Dissipation (continued)

During active current-limit operation, the SLG59M1709V's power dissipation can be calculated by taking into account the voltage drop across the load switch ($V_{IN}-V_{OUT}$) and the magnitude of the output current in active current-limit operation (I_{ACL}):

$$PD = (V_{IN}-V_{OUT}) \times I_{ACL} \text{ or}$$

$$PD = (V_{IN} - (R_{LOAD} \times I_{ACL})) \times I_{ACL}$$

where:

PD = Power dissipation, in Watts (W)
 V_{IN} = Input Voltage, in Volts (V)
 R_{LOAD} = Load Resistance, in Ohms (Ω)
 I_{ACL} = Output limited current, in Amps (A)
 $V_{OUT} = R_{LOAD} \times I_{ACL}$

For more information on GreenFET load switch features, please visit our website and see App Note "AN-1068 GreenFET and High Voltage GreenFET Load Switch Basics".

SLG59M1709V

An Ultra-small, 4 mΩ, 4 A Load Switch
with Multiple Protection Features

Layout Guidelines:

1. The VDD pin needs a 0.1 μF (or larger) external capacitor to smooth pulses from the power supply. Locate this capacitor as close as possible to the SLG59M1709V's pin 1.
2. Since the VIN and VOUT pins dissipate most of the heat generated during high-load current operation, it is highly recommended to make power traces as short, direct, and wide as possible. A good practice is to make power traces with an absolute minimum widths of 15 mils (0.381 mm) per Ampere. A representative layout, shown in Figure 4, illustrates proper techniques for heat to transfer as efficiently as possible out of the device;
3. To minimize the effects of parasitic trace inductance on normal operation, it is recommended to connect input C_{IN} and output C_{LOAD} low-ESR capacitors as close as possible to the SLG59M1709V's VIN and VOUT pins;
4. The GND pin should be connected to system analog or power ground plane.

SLG59M1709V Evaluation Board:

A GreenFET Evaluation Board for SLG59M1709V is designed according to the statements above and is illustrated on Figure 4. Please note that evaluation board has D_Sense and S_Sense pads. They cannot carry high currents and dedicated only for $R_{DS(ON)}$ evaluation.
